Poisson-Dirichlet Distribution

Definition (Kingman 1978; Pitman 1995)

For $0 \leq \alpha < 1$ and $\theta > -\alpha$, or $\alpha < 0$ and $\theta = -\alpha m$, $m \in \mathbb{N}$, let

$$P_1 = W_1, \quad P_i = W_i \prod_{j=1}^{i-1} (1 - W_j), \quad i = 2, 3, \dots,$$

with $W_i \sim \mathbf{Beta}(1 - \alpha, \theta + i\alpha)$, iid. The ranked sequence of (P_i) is the 2-parameter Poisson-Dirichlet distribution $\mathbf{PD}(\alpha, \theta)$.

Remark

- ▶ $\mathbf{P}(\cdot) = \sum_{i=1}^{\infty} P_i \delta_{Y_i}(\cdot)$ is the 2-parameter Dirichlet process.
- ▶ Most general such that (P_i) is invariant under size-biased permutation.

Pitman's Random Partition

A partition of $\mathbf{n} \in \mathbb{N}$ by integers is identified by multiplicity (\mathbf{c}_i) such that

$$\|\mathbf{c}\| := \sum_{i=1}^n c_i = k_n, \quad |\mathbf{c}| := \sum_{i=1}^n i c_i = n.$$

Definition (Ewens 1972; Pitman 1992)

An exchangeable random partition

$$\mathbf{P}((\mathbf{C}_i) = (\mathbf{c}_i), \mathbf{K}_n = \mathbf{k}) = \frac{\left(\frac{\theta}{\alpha}\right)_{\mathbf{k}}}{(\theta)_{\mathbf{n}}} (-1)^{n-k} n! \prod_{j=1}^n \binom{\alpha}{j}^{c_j} \frac{1}{c_j!},$$

where $(\theta)_{\mathbf{n}} = \theta(\theta + 1) \cdots (\theta + n - 1)$.

The sampling distribution from $\mathbf{PD}(\alpha, \theta)$; the ranked sizes converges as

$$\mathbf{n}^{-1}(\mathbf{L}_1^{(\mathbf{n})}, \mathbf{L}_2^{(\mathbf{n})}, \dots) \xrightarrow{d} (\mathbf{P}_{(1)}, \mathbf{P}_{(2)}, \dots), \quad \mathbf{n} \rightarrow \infty,$$

but how are the limiting distributions and in $\mathbf{o}(\mathbf{n})$?

Incomplete Dirichlet Integrals

A collection of random variables $(\mathbf{Y}_1, \dots, \mathbf{Y}_d) \sim \mathbf{Dir}(\boldsymbol{\nu}; \boldsymbol{\rho})$ if the pdf is

$$\frac{\Gamma(\boldsymbol{\rho} + \mathbf{d}\boldsymbol{\nu})}{\Gamma(\boldsymbol{\rho})\Gamma(\boldsymbol{\nu})^d} \left(\mathbf{1} - \sum_{j=1}^d \mathbf{y}_j \right)^{\boldsymbol{\rho}-1} \prod_{i=1}^d \mathbf{y}_i^{\boldsymbol{\nu}-1}$$

over the simplex $\boldsymbol{\Delta}_d = \{\mathbf{0} < \mathbf{y}_i, i = 1, \dots, d, \sum_{j=1}^d \mathbf{y}_j < \mathbf{1}\}$. Let us introduce an extension of the incomplete Dirichlet integrals of Type I (Sobel et al. 1970)

$$\mathcal{I}_{\mathbf{p}, \mathbf{q}}^{(d)}(\boldsymbol{\nu}; \boldsymbol{\rho}) := \frac{\Gamma(\boldsymbol{\rho} + \mathbf{d}\boldsymbol{\nu})}{\Gamma(\boldsymbol{\rho})\Gamma(\boldsymbol{\nu})^d} \int_{\boldsymbol{\Delta}_d(\mathbf{p}, \mathbf{q})} \left(\mathbf{1} - \sum_{j=1}^d \mathbf{y}_j \right)^{\boldsymbol{\rho}-1} \prod_{i=1}^d \mathbf{y}_i^{\boldsymbol{\nu}-1} d\mathbf{y}_i,$$

where $\boldsymbol{\Delta}_d(\mathbf{p}, \mathbf{q}) = \{\mathbf{p} < \mathbf{y}_i, i = 1, \dots, d; \sum_{j=1}^d \mathbf{y}_j < \mathbf{1} - \mathbf{q}\}$.

Limiting Distribution of Maximum

For $\alpha < \mathbf{0}$ and $\theta = -\alpha\mathbf{m}$, $\mathbf{m} \in \mathbb{N}$, $(\mathbf{P}_i) \sim \text{Dir}(-\alpha)$, so we skip and assume $\alpha \geq \mathbf{0}$.

Theorem (Pitman & Yor 1997)

For $\mathbf{0} \leq \alpha < \mathbf{1}$ and $\theta > -\alpha$, the maximum, $\mathbf{P}_{(1)}$, has cdf

$$\rho_{\alpha, \theta}(\mathbf{x}) = \mathbf{1} + \sum_{k=1}^{\lfloor \mathbf{x}^{-1} \rfloor} \frac{\alpha^{-k} (\theta)_{k:\alpha}}{k!} \mathcal{I}_{\mathbf{x}, 0}^{(k)}(-\alpha; k\alpha + \theta),$$

where $(\theta)_{k:\alpha} = \theta(\theta + \alpha) \cdots (\theta + (k-1)\alpha)$.

Remark

- ▶ Appears as the limiting distribution of $\mathbf{n}^{-1} \mathbf{L}_1^{(n)}$ with $\mathbf{r}/\mathbf{n} \rightarrow \mathbf{x}$.
- ▶ In the number theory $\rho_{0,1}(\mathbf{u})$ is known as **Dickman's function** (1930) on the distribution of the smooth numbers.

Limiting Distribution of Minimum

Theorem (Arratia, Barbour, Tavaré 2003)

For $\alpha = \mathbf{0}$ and $\theta > \mathbf{0}$, the minimum, $\mathbf{L}_{\mathbf{K}_n}^{(n)}$, has

$$\mathbf{P}(\mathbf{L}_{\mathbf{K}_n}^{(n)} > \mathbf{r}) \sim \Gamma(\theta) (\mathbf{n}\mathbf{x})^{-\theta} \omega_{\theta}(\mathbf{x}), \quad \mathbf{n}, \mathbf{r} \rightarrow \infty, \quad \mathbf{r}/\mathbf{n} \rightarrow \mathbf{x},$$

where

$$\omega_{\theta}(\mathbf{x}) = \theta \mathbf{x}^{\theta} \left\{ 1 + \sum_{1 \leq \mathbf{k} \leq \mathbf{x}^{-1} - 1} \frac{\theta^{\mathbf{k}}}{(\mathbf{k} + 1)!} \mathcal{I}_{\mathbf{x}, \mathbf{x}}^{(\mathbf{k})}(\mathbf{0}; \mathbf{0}) \right\}.$$

Remark

The distribution is degenerate. In the number theory $\omega_1(\mathbf{x})$ is known as **Buchstab's function** (1937) on the distribution of the rough numbers.

Limiting Distribution of Minimum (cont.)

Theorem (Arratia, Tavaré 1992)

For $\alpha = 0$ and $\theta > 0$, the minimum, $\mathbf{L}_{\mathbf{K}_n}^{(n)}$, has

$$\mathbf{P}(\mathbf{L}_{\mathbf{K}_n}^{(n)} > r) \sim \exp\left(-\theta \sum_{j=1}^{r-1} j^{-1}\right), \quad \mathbf{n} \rightarrow \infty, \quad r = o(\mathbf{n}).$$

For $0 < \alpha < 1$ and $\theta > -\alpha$, the limiting distribution has not been considered, but $\mathbf{L}_{\mathbf{k}_n}^{(n)} \xrightarrow{\mathbf{P}} \mathbf{1}$, since

Theorem (Yamato & Sibuya 2000)

$$\mathbf{n}^{-\alpha}(\mathbf{C}_1, \dots, \mathbf{C}_m) \xrightarrow{\mathbf{d}} (\mathbf{p}_\alpha(\mathbf{1}), \dots, \mathbf{p}_\alpha(\mathbf{m}))\mathbf{M}, \quad i = 1, 2, \dots, m, \quad \mathbf{n} \rightarrow \infty,$$

where $\mathbf{p}_\alpha(\mathbf{i}) = \binom{\alpha}{\mathbf{i}} (-\mathbf{1})^{\mathbf{i}+1}$ is pmf of Sibuya's distribution (1979)

and \mathbf{M} has pdf of $\mathbf{x}^{\theta/\alpha} \times$ Mittag-Leffler's distribution.

Outline

In summary, known facts are

r	$P(L_1^{(n)} < r)$		$P(L_{K_n}^{(n)} > r)$	
	$O(n)$	$o(n)$	$O(n)$	$o(n)$
$\alpha < 0$			Dir($-\alpha$) and back to Fisher (1929)	
$\alpha = 0$	Dickman ¹	?	Buchstab ² (degenerate)	Poisson ³
$\alpha > 0$	Dickman ¹	?	? (degenerate ⁴)	? (degenerate ⁴)

1 Pitman & Yor (1997); 2 Arratia et al (2003); 3 Arratia & Tavaré (1992); 4 Yamato & Sibuya (2000). But for the random permutation ($\alpha = 0$, $\theta = 1$) it is a classic back to Goncharov (1942), Shepp & Lloyd (1966).

In this talk, the **table is filled out** with reproductions. All results have been obtained by probability techniques, but here **singularity analysis in analytic combinatorics** (Flajolet & Odolzyko 1990) is employed.

Use of Sufficiency

Assume α is known.

$$\begin{aligned}P(\mathbf{K}_n = \mathbf{k}) &= \sum_{\|\mathbf{c}\|=\mathbf{k}} P((\mathbf{C}_i) = (\mathbf{c}_i), \mathbf{K}_n = \mathbf{k}) \\&= \frac{\left(\frac{\theta}{\alpha}\right)_{\mathbf{k}}}{(\theta)_{\mathbf{n}}} (-1)^{n-\mathbf{k}} \mathbf{n}! \sum_{\|\mathbf{c}\|=\mathbf{k}} \prod_{j=1}^n \binom{\alpha}{j}^{c_j} \frac{1}{c_j!} \\&= \frac{\left(\frac{\theta}{\alpha}\right)_{\mathbf{k}}}{(\theta)_{\mathbf{n}}} (-1)^{n-\mathbf{k}} \mathbf{C}(\mathbf{n}, \mathbf{k}; \alpha).\end{aligned}$$

\mathbf{K}_n is the complete and sufficient statistic of θ :

$$P((\mathbf{C}_i) = (\mathbf{c}_i) | \mathbf{K}_n = \mathbf{k}) = \frac{\mathbf{n}!}{\mathbf{C}(\mathbf{n}, \mathbf{k}; \alpha)} \prod_{j=1}^n \binom{\alpha}{j}^{c_j} \frac{1}{c_j!},$$

where $\mathbf{C}(\mathbf{n}, \mathbf{k}; \alpha)$ is the **generalized factorial coefficient** .

Generalized Factorial Coefficient

A generalized factorial of \mathbf{t} of order \mathbf{n} and scale parameter is α ,

$$[\alpha \mathbf{t}]_{\mathbf{n}} = \alpha \mathbf{t}(\alpha \mathbf{t} - \mathbf{1}) \cdots (\alpha \mathbf{t} - \mathbf{n} + \mathbf{1}), \quad [\alpha \mathbf{t}]_0 = \mathbf{1}.$$

The generalized factorial coefficients is defined as (Charalambides 2005)

$$[\alpha \mathbf{t}]_{\mathbf{n}} = \sum_{\mathbf{k}=1}^{\mathbf{n}} \mathbf{C}(\mathbf{n}, \mathbf{k}; \alpha) [\mathbf{t}]_{\mathbf{k}},$$

with the exponential generating function (egf):

$$\sum_{\mathbf{n}=\mathbf{k}}^{\infty} \mathbf{C}(\mathbf{n}, \mathbf{k}; \alpha) \frac{\mathbf{u}^{\mathbf{n}}}{\mathbf{n}!} = \frac{\mathbf{1}}{\mathbf{k}!} ((\mathbf{1} + \mathbf{u})^{\alpha} - \mathbf{1})^{\mathbf{k}}.$$

Generalized Factorial Coefficient (cont.)

Suppose $\alpha (\geq \mathbf{n}) \in \mathbb{N}$ and partitions of \mathbf{n} like balls into \mathbf{k} urns. Each urn consists of α distinguishable cells and each cell accept one ball.

$$\sum_{|\mathbf{a}|=\mathbf{n}} \prod_{j=1}^{\mathbf{k}} \binom{\alpha}{\mathbf{a}_j}.$$

Let $c_i = |\{j : a_j = i\}|$.

$$\sum_{\|\mathbf{c}\|=\mathbf{k}} \frac{\mathbf{k}!}{\mathbf{c}_1! \mathbf{c}_2! \cdots \mathbf{c}_n!} \prod_{j=1}^{\mathbf{n}} \binom{\alpha}{j}^{c_j} = \frac{\mathbf{k}!}{\mathbf{n}!} \mathbf{C}(\mathbf{n}, \mathbf{k}; \alpha).$$

Example ($\mathbf{K}_4 = 2$)

$(1, 2)(1, 2)$	$[\alpha]_2^2 / (2!)^2$
$(1)(1, 2, 3), (1, 2, 3)(1)$	$2\alpha[\alpha]_3 / (1! \cdot 3!)$

Therefore $\mathbf{C}(4, 2; \alpha) = 3[\alpha]_2^2 + 4\alpha[\alpha]_3$.

Associated Generalized Factorial Coefficients

If each urn has **at least r balls**,

$$n! \sum_{c_j < r=0} \prod_{j=r}^n \binom{\alpha}{j}^{c_j} \frac{1}{c_j!} =: C_r(n, k; \alpha), \quad n = rk, rk + 1, \dots$$

which is known as the **r -associated** generalized factorial coefficient (Charalambides 2005). Let us define an extension, in which (c_i) are restricted such that the **i -th smallest has at least r balls**.

Definition (Mano 2013)

An extension of the **r -associated** generalized factorial coefficient is

$$C_r^{(i)}(n, k; \alpha) := n! \sum_{\sum_{j=1}^{r-1} c_j < i} \prod_{j=r}^n \binom{\alpha}{j}^{c_j} \frac{1}{c_j!}, \quad i = 1, \dots, k,$$

where $n = rk - (i - 1)(r - 1), rk - (i - 1)(r - 1) + 1, \dots$

Exact Marginal Distribution

Definition (cont.)

$$C^{r(i)}(\mathbf{n}, \mathbf{k}; \alpha) := n! \sum_{\sum_{j=r+1}^n c_j < i} \prod_{j=r}^n \binom{\alpha}{j}^{c_j} \frac{1}{c_j!}, \quad i = 1, \dots, k,$$

where $\mathbf{n} = \mathbf{k}, \dots, r\mathbf{k}$ for $i = 1$ and $\mathbf{n} = \mathbf{k}, \mathbf{k} + 1, \dots$ for $i > 1$.

Lemma

The i -th smallest, $L_{K_n - i + 1}^{(n)}$, has

$$P(L_{K_n - i + 1}^{(n)} \geq r) = \sum_{k=1}^{\lfloor \frac{n+(i-1)(r-1)}{r} \rfloor} \frac{(-1)^n (\theta)_{k;\alpha}}{(-\alpha)^k (\theta)_n} C_r^{(i)}(\mathbf{n}, \mathbf{k}; \alpha).$$

and the i -th largest, $L_i^{(n)}$, has cdf

$$P(L_i^{(n)} \leq r) = \sum_{k=\lceil \frac{n}{r} \rceil, 1}^n \frac{(-1)^n (\theta)_{k;\alpha}}{(-\alpha)^k (\theta)_n} C_r^{(i)}(\mathbf{n}, \mathbf{k}; \alpha).$$

Exponential Generating Functions

Lemma

$$\sum_{n=k}^{rk} C^r(n, k; \alpha) \frac{u^n}{n!} = \frac{1}{k!} \left(\sum_{j=1}^r \binom{\alpha}{j} u^j \right)^k$$

and

$$\sum_{n=rk}^{\infty} C_r(n, k; \alpha) \frac{u^n}{n!} = \frac{1}{k!} \left((1+u)^\alpha - \sum_{j=0}^{r-1} \binom{\alpha}{j} u^j \right)^k.$$

Proof.

By combinatorics. But more general assertion is possible via **Faà di Bruno's formula** (1855; but Arbogast 1800; Comtet 1974; Shimizu et al. 2000); for $\mathbf{h}(\mathbf{u}) = \mathbf{g}(\mathbf{f}(\mathbf{u}))$,

$$\mathbf{h}^{(n)}(\mathbf{u}) = \sum_{d=1}^n \mathbf{g}^{(d)}(\mathbf{f}(\mathbf{u})) \sum_{\|\mathbf{c}\|=d} n! \prod_{j=1}^n \left(\frac{f^{(j)}(\mathbf{u})}{j!} \right)^{c_j} \frac{1}{c_j!},$$

Inversion Formulae

Proposition (Shimizu in private communication)

If an egf a \mathbf{r} -associated number $\mathbf{G}_r(\mathbf{n}, \mathbf{k})$ is defined in terms of a series \mathbf{q}_j ,

$$\sum_{n=rk}^{\infty} \mathbf{G}_r(\mathbf{n}, \mathbf{k}) \frac{u^n}{n!} = \frac{1}{k!} \left(\sum_{j=r}^{\infty} \mathbf{q}_j u^j \right)^k.$$

Then the number has an expression

$$\mathbf{G}_r(\mathbf{n}, \mathbf{k}) = n! \sum_{c_j < r=0} \prod_{j=r}^n \frac{\mathbf{q}_j^{c_j}}{c_j!}, \quad \mathbf{n} = rk, rk + 1, \dots$$

Remark

Similar formula holds for $\mathbf{G}^r(\mathbf{n}, \mathbf{k})$. \mathbf{j}^{-1} gives the \mathbf{r} -associated Stirling number of the first kind, $\binom{\alpha}{\mathbf{j}}$ gives the \mathbf{r} -associated generalized factorial coefficient.

Minimum with $\alpha > 0$ and $r = o(n)$

Theorem

For $0 < \alpha < 1$ and $\theta > \alpha$, the minimum, $L_{K_n}^{(n)}$, has

$$P(L_{K_n} > r) \sim \frac{\Gamma(1 + \theta)}{\Gamma(1 - \alpha)} n^{-\theta - \alpha} (c_\alpha(r - 1))^{-1 - \frac{\theta}{\alpha}}, \quad n \rightarrow \infty, \quad r = o(n),$$

where $r = 2, 3, \dots$ and $c_\alpha(r)$ is cdf of Sibuya's distribution.

Proof.

Applying the Cauchy-Goursat theorem to the egf,

$$P(L_{K_n} > r) = \frac{n!}{[\theta]_n} \frac{1}{2\pi\sqrt{-1}} \oint \frac{(f_{\alpha,r}(u))^{-\frac{\theta}{\alpha}}}{u^{n+1}} du,$$

$$\text{where } f_{\alpha,r}(u) = (1 - u)^\alpha - \sum_{j=1}^{r-1} \binom{\alpha}{j} (-u)^j.$$

Minimum with $\alpha > 0$ and $r = o(n)$ (cont.)

Proof. (cont.)

According to Rouché's theorem, we can show that $f_{\alpha,r}(\mathbf{u}) = \mathbf{0}$ has no roots in $|\mathbf{u}| \leq 1$. Therefore taking the cut $[1, \infty)$ and $\eta > 0$ we can deform the contour for the Cauchy integral without changing the value.

$\gamma_2, \gamma_1, \gamma_4$ avoid the cut with distance $1/n$. Contribution comes from the part of the contour, which is similar to Hankel's contour for the asymptotic expansion of the Gamma function. Taking $n \rightarrow \infty$ the theorem follows. \square

Maximum with $\alpha = 0$ and $\mathbf{r} = \mathbf{o}(\mathbf{n})$

Theorem

For $\alpha = 0$ and $\theta > 0$, the maximum, $\mathbf{L}_1^{(\mathbf{n})}$, has cdf

$$\mathbf{P}(\mathbf{L}_1^{(\mathbf{n})} < \mathbf{r}) \sim \frac{\Gamma(\theta)\mathbf{n}^{-\theta+1/2}}{\sqrt{2\pi\mathbf{r}}} \sum_{j=0}^{r-1} \rho_{\theta,r,n,j}^{-\mathbf{n}} \exp\left(\theta \sum_{k=1}^r \frac{\rho_{\theta,r,n,j}^k}{k}\right), \mathbf{n} \rightarrow \infty,$$

where $\mathbf{r} = \mathbf{o}(\mathbf{n})$ and $\rho_{\theta,r,n,j} \sim (\mathbf{n}/\theta)^{1/r}$, $j = 0, 1, \dots, r-1$ are the roots of the equation $\mathbf{u} + \mathbf{u}^2 + \dots + \mathbf{u}^r = (\mathbf{n} + 1)/\theta$.

Proof.

Applying the Cauchy-Goursat theorem to egf, we have an integral expression. Taking contour as a polygon which goes through each saddle point (absolute values are $\rho_{\theta,r,n,j}$) along the direction of the steepest descent, the Cauchy integral is evaluated. □

Summary

- ▶ Exact formule for marginal distributions of ranked sequence were obtained in terms of an extension of the associated generalized factorial coefficient.
- ▶ For the limiting distributions, singularity analysis yielded

r	$P(L_1^{(n)} < r)$		$P(L_{K_n}^{(n)} > r)$	
	$O(n)$	$o(n)$	$O(n)$	$o(n)$
$\alpha < 0$	Dickman	0	$\mathcal{I}_{x,x}^{(m-1)}(-\alpha, -\alpha)$	$1 - a_r n^\alpha$
$\alpha = 0$	Dickman	$b_r n^{1/2-\theta} \rho_r^{-n}$	Buchstab $\cdot n^{-\theta}$	Poisson
$\alpha > 0$	Dickman	$c_r n^{\theta/\alpha-\theta} \rho_r^{-n}$	$n^{-\theta-\alpha}$	Sibuya $\cdot n^{-\theta-\alpha}$
